

Assessment Methods for Data-Moderate Stocks
Report of the Methodology Review Panel Meeting

National Marine Fisheries Service (NMFS)
Alaska Fisheries Science Center (AFSC)
Seattle, Washington
26-29 June 2012

Methodology Review Panel Members:

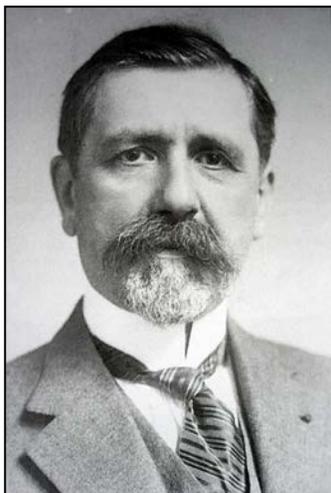

Mathew Cieri, Center for Independent Experts (CIE)
Martin Dorn (Chair), Scientific and Statistical Committee (SSC), NMFS, AFSC
Vladlena Gertseva, SSC, NMFS, Northwest Fisheries Science Center
Cynthia Jones, CIE
André Punt, SSC, University of Washington

Panel advisors:

John DeVore, PFMC Staff
Corey Niles, Groundfish Management Team
Gerry Richter, Groundfish Advisory Panel

Technical Team:

Emil Aalto, University of California, Davis
Linsey Arnold, Oregon State University
Jason Cope, NMFS, NWFSC
Edward Dick, NMFS, SWFSC
Kristen Honey, Stanford University
Alec MacCall, NMFS, SWFSC
James Thorson, NMFS, NWFSC
Chantel Wetzel, NWFSC, University of Washington

Émile Borel (1871-1956)

1. OVERVIEW

A review of data-moderate assessment methods was conducted by a Methodology Review Panel (Panel) at the Alaska Fisheries Science Center, Seattle, WA, during 26-29 June 2012. The review panel included three SSC members and two CIE reviewers. The Panel followed draft Terms of Reference for Stock Assessment Methodology Reviews (March 2012). Dr. James Hastie opened the meeting on behalf of the Northwest Fisheries Science Center, welcomed the participants, and introduced Dr. Martin Dorn, the panel chair. The Panel was provided extensive background material, including a number of primary documents, through an FTP site, two weeks prior to the review meeting. The Technical Team gave several presentations to the Panel during the meeting, and responded to panel requests for additional information.

The Pacific Fishery Management Council (the Council) approved a data-moderate assessment workshop to be held in 2012 at its September 2011 meeting. The workshop was planned as a follow-up to the review panel meeting in April 2011 that reviewed assessment methods for data-poor stocks. At that meeting, the Panel endorsed the use of several catch-only methods (DCAC, DB-SRA, and Simple Stock Synthesis (SSS)) for category 3 stocks, and considered new assessment methods for data-moderate category 2 stocks. The defining distinction between category 3 and category 2 stocks is that stock abundance trend information is incorporated in the assessment. The April 2011 review panel did not endorse any of the methods proposed for category 2 stocks, since these methods were not sufficiently developed at that time. The Panel recommended the following:

“To continue the progress that has been made, the Panel recommends that a similar off-year STAR Panel review be scheduled to further develop and finalize methods and to review example applications. The Panel suggests a few common data sets be used across all candidate methods. The meeting would involve participants from at least the NWFSC, the SWFSC, and various academic institutions. Methods should be sufficiently developed by the 2015-16 groundfish management cycle that it would be reasonable to bring forward a number of candidate category 2 stock assessments using simple assessment models for review at a STAR Panel in 2013.”

The goal of this meeting was to review progress in implementing the recommendations of the April 2011 workshop, and further discuss how to best conduct and review data-poor and data-moderate assessments within the Council process. In particular, the Panel evaluated several proposed refinements to catch-only methods, reviewed two proposed methods for category 2 stock assessments that incorporate abundance indices, evaluated performance of both methods in trial applications, and discussed data available to inform abundance trends for category 2 stocks.

The Panel agreed that substantial progress that has been made since the last review panel meeting. The Panel concluded that two data-moderate assessment methods, XDB-SRA and exSSS, are sufficiently well developed to form the basis for category 2 assessments in the next assessment cycle. However, simulation testing was recommended to further evaluate utility of both methods. The Panel also endorsed several refinements to data-poor methods, and provided recommendations on how to further improve inputs for DB-SRA and SSS. A comparison of data-moderate assessments results with outputs from full assessments suggests that data-

moderate methods can provide improved results over data-poor approaches, such as DB-SRA and SSS. The Panel recommends that the data-moderate assessments be used for setting OFLs, ABCs, and ACLs. Data-moderate assessments, however, have greater uncertainty than full assessments, and the Panel recommends that a two-stage process be adopted for status determination, in which data-moderate assessments are used to evaluate whether a stock is of concern, followed by a full assessment (if warranted), which would utilize all available information.

The Chair thanked the NWFSC for hosting the meeting, acknowledged the assistance of AFSC in providing a meeting room and helping with meeting logistics, and thanked the participants for the creative and constructive atmosphere during the review, the results of which should help inform the Council and its advisory bodies determine the best available science for the assessment of groundfish.

2. COMMENTS ON THE TECHNICAL MERITS AND/OR DEFICIENCIES OF THE METHODOLOGY

2.1. Refinements to Catch-Only Methods for Category 3 stocks

DCAC and DB-SRA have been used by the Council to estimate OFLs and set harvest specifications for category 3 stocks. Both methods require four types of input, including a ratio of B_{MSY} to B_0 , a ratio of F_{MSY} to M , natural mortality (M), and reduction in abundance, or delta parameter (which represents stock depletion). At the meeting, progress with efforts to better inform these inputs was presented.

2.1.1 B_{MSY}/B_0 ratio

Dr. James Thorson presented a meta-analysis that treats the Pella-Tomlinson shape parameter (and by extension B_{MSY}/B_0) as a random effect while fitting surplus production models to catch time series and stock assessment estimates of spawning biomass from the RAM Legacy Stock Assessment Database. The results demonstrated that B_{MSY}/B_0 differs among taxonomic orders, and is generally lower for Clupeiformes and higher for Scorpaeniformes. There is also a significant correlation between B_{MSY}/B_0 and maximum body size both within and between taxonomic orders. The estimate of B_{MSY}/B_0 for all stocks pooled was approximately 40%, which corresponds well with assumptions used in the Council process, although the mean values estimated for B_{MSY}/B_0 for Scorpaeniformes (46%) and Pleuronectiformes (40%) were higher than currently assumed (40% and 25% respectively) by the Council.

The Panel found this analysis to be potentially useful in better informing the prior distribution of B_{MSY}/B_0 used in DB-SRA. To help interpret results of the analysis, the Panel made two requests (*Requests A and B*, below).

2.1.2 F_{MSY}/M ratio

Dr. Thorson presented results of Zhou et al. (2012), who assembled a database of F_{TARGET} estimates from assessed bony and cartilaginous species, and compared these estimates with estimates of natural mortality (M) within a hierarchical Bayesian model with measurement error. F/M ratios were estimated separately for different F_{TARGET} methods (i.e., F_{MSY} , F_{proxy} , and F set at 50% of an estimate of the intrinsic growth rate r), and taxonomic groups (bony vs. cartilaginous fishes). The estimate of mean F_{MSY}/M ratio was 0.41 for cartilaginous fish and 0.86 for bony

fish before bias-correction. Application of the delta-method (while including bias-correction for M as well as F given M) yielded an estimate of F_{MSY}/M of 0.97 for bony fishes and 0.46 for cartilaginous fishes.

To help interpret results of the analysis, the Panel made one request (*Request C*, below).

2.1.3 M/k ratio

Dr. Thorson presented a new “Meta-analysis using Stock Assessment Software” (MESAS) framework to conduct meta-analyses, with specific application to the life history invariant M/k using the Stock Synthesis software and inputs used for peer-reviewed assessments of 11 stocks on the U.S. West Coast. This framework approximates the posterior distribution for the parameters of the stock assessment except natural mortality M and the von Bertalanffy growth coefficient k using marginal likelihood (while treating M given k as a random effect for each stock), and finds an expected value for M given k of 1.26 for rockfishes, with a coefficient of variation for M given k of 0.68.

The Panel notes that this approach uses the available data in a more appropriate matter, but the coefficient of variation for M given k was not lower than those for other methods which have been used in Council assessments.

2.1.4 Natural Mortality

Dr. Jason Cope gave a brief outline of Dr. Owen Hamel's work on developing a prior distribution for natural mortality (M) to be used in stock assessments. This approach combines existing methods to develop a meta-analytical prior for M. This method appears to be relevant to both full assessment and assessments for data-moderate stocks. The method has been applied in several assessments used by the Council, but has not gone through peer-review, or review by the Council's Statistical and Scientific Committee (SSC).

Complete details of this approach were not available (as Dr. Hamel was away on other work obligations). The Panel was unable to properly evaluate the specifics of the method and, therefore, and was unable to recommend it to be used in catch-only (as well as data-moderate) assessment methods at present. The Panel recommended this analysis be documented and brought for SSC review, ideally before the next assessment cycle.

2.1.5 Delta

Dr. Cope presented a relationship between the Productivity-Susceptibility Analysis (PSA, Patrick et al. (2010)) vulnerability score and depletion for Council-approved assessed species. He showed that the PSA vulnerability scores are correlated with the estimated delta values for the 31 previously-assessed stocks used to evaluate the performance of DB-SRA. This relationship, therefore, can be used to inform the prior distribution on delta (or depletion), and thus improve this input for catch-only models. Drs. E.J. Dick and Alec MacCall used PSA vulnerability scores to improve specification of the delta parameter in DB-SRA, which allowed DB-SRA to use stock-specific delta priors with a potential gain in performance. Although improved performance was demonstrated for a number of stocks, low values of delta (those that correspond to stocks that had declined very little in abundance) tended to result in poorer performance of DB-SRA, and the original fixed value of delta led to better estimates of OFL for those stocks. Drs. Dick

and MacCall proposed a modification where the regression value of delta was used for vulnerable stocks, but a minimum delta of 0.5 was used for less vulnerable stocks.

The Panel agreed that using PSA vulnerability scores to inform delta priors is an improvement to catch-only methods, and recommended that this approach be used in both DB-SRA and SSS. The Panel, however, recommended that instead of using a subjectively selected minimal delta value of 0.5 for less vulnerable stocks, three vulnerability bins with breaks at PSA scores of 1.8 and 2.2 (as defined in Cope et al. 2011) be used, and the delta values associated with each bin be set to the mean for the bin. Such an approach allows the use of PSA results already used in the Council process to define bins. This approach should also be used for the extended versions of DB-SRA and SSS where applicable.

2.1.6 Modified Production Function

Emil Aalto presented an analysis of a DB-SRA correction term proposed by Drs. Dick and MacCall to address a misspecification in the original DB-SRA production function. When the biomass has changed between time t (when recruitment is produced) and time $t+a$ (when that recruitment joins the exploitable stock), the amount of recruitment needed to replace losses due to natural mortality (M) has also changed. For example, if the stock has declined, some of the recruitment produced at the initial higher biomass appears as spurious net production, when it joins an exploitable biomass that is smaller than that which produced it. The proposed correction term eliminates the spurious production due to trends in abundance. The Panel agreed that this modification is an improvement of the method previously used (see also *Request D* below).

2.1.7 Requests by the Panel and Responses by the Technical Team

Request A: For the B_{MSY}/B_0 analysis (presented by Dr. Thorson), show the fits of outputs from the random effects and meta-analytic models presented to data for West Coast rockfish.

Rationale: To better interpret the results of the analysis, and further evaluate their utility for catch-only methods.

Response: The numbers generated using the global assessment database were found to be different from estimates produced when the database was limited to West Coast and Alaskan species only, probably due to decrease in sample sizes when using only a subset of species.

The Panel did not have sufficient information to thoroughly evaluate how the analyses were conducted and, hence, explore possible reasons for differences (particularly notable for Pleuronectiformes) between results presented and the proxy values currently assumed within the Council process. Therefore, the Panel does not recommend using results of the analysis presented to inform the prior distribution for B_{MSY}/B_0 , but encourages further efforts in refining inputs required for catch-only methods.

Request B: Provide summaries of B_{MSY}/B_0 for West Coast and Alaska stocks, grouping species into rockfish, flatfish, elasmobranchs, others.

Rationale: To better interpret the results of the analysis, and further evaluate their utility for catch-only methods.

Response: see response to *Request A*.

Request C: Provide summary of F_{MSY}/M for West Coast and Alaska stocks, grouping species into rockfish, flatfish, elasmobranchs, others.

Rationale: To better interpret results of the analysis, and further evaluate their utility for catch-only methods.

Response: The database assembled by Zhou et al. (2012) does not designate data by region so the request could not be fulfilled.

The Panel did not have sufficient information explore possible reasons for differences between results presented and the values currently assumed for DB-SRA and DCAC. Therefore, the Panel does not recommend using results of the analysis presented to inform the prior distribution for F_{MSY}/M , but encourages further efforts in refining the approach. The expected F_{MSY}/M value currently assumed for DB-SRA and DCAC is 0.8, which is reasonably consistent with the results of the Zhou et al. (2012) meta-analysis.

Request D: Calculate OFL distributions for 31 stocks, compare OFLs generated by DB-SRA with assessment results (by species), create bias correction distributions by PSA species groups, apply these bias-correction distributions to each species, generate a distribution of the absolute value of $x-1$ (where x is a draw from bias-corrected distribution), and compare the results for all four DB-SRA versions presented and discussed: (1) original DB-SRA (with delta of 0.6); (2) version with M correction applied (with delta of 0.6); (3) version with M correction and with three vulnerability bins (as identified in Cope et al. (2011)) used to inform delta; (4) with M correction and delta informed by depletion-vulnerability regression.

Rationale: To further evaluate the modifications proposed to the original DB-SRA, and particularly the use of vulnerability bins (rather than the depletion-vulnerability regression) to inform delta.

Response: The results of the requested runs were presented (Table 1). These results demonstrated that the version of DB-SA with vulnerability bins (version 3) outperformed the other two versions. The Panel recommends that future applications of DB-SRA include the correction for M as well as distributions for delta by PSA vulnerability bin.

2.2. Review and adoption of data-moderate methods

2.2.1 Stock Synthesis using only Catch and Index Time Series (SS-CI)

Dr. Jason Cope presented the Simple Stock Synthesis (SSS) and the extended Simple Stock Synthesis (exSSS) methods. SSS is based on sampling parameters (steepness, natural mortality and depletion) from prior distributions and using SS3 to solve for virgin recruitment (R_0) given inputs for selectivity, growth, and fecundity. ExSSS extends SSS by allowing index data (and potentially length and age data) to be used for parameter estimation. Unlike SSS, parameter estimation for exSSS is either based on maximum likelihood or Bayesian (MCMC) methods. Both SSS and exSSS assume that recruitment is related deterministically to the stock-recruitment relationship. The outputs from SSS and exSSS include biomass trajectories, as well as estimates of (and measures of uncertainty for) the OFL. SSS_v is a variant of SSS in which the prior for depletion is based on the results of a regression of depletion on the PSA vulnerability score. This approach will be replaced in future implementations by the procedure of binning by vulnerability score as described in Section 2.1.5 above. The methods were applied for illustrative purposes to data for seven stocks of west coast groundfish and the results compared to those of the associated full assessments. These applications were intended to show a progression of assessments and

data usage from most data-limited (SSS) to full assessment (SS). Five of the seven comparisons were able to replicate the SS dynamics, including the ability to include the more complex treatment of fishery-dependent data in the petrale sole assessment. Two exSSS models (spiny dogfish and sablefish) were unable to replicate the SS model outputs, but were diagnosable as questionable without comparing them to the SS models.

The version of SSS presented to the Panel differs from the one presented to the April 2011 Panel by using a Monte Carlo method for parameter estimation (rather than a MCMC method in which priors are imposed on both depletion and R_0) and by exploring a variant of SSS in which the distribution for depletion is informed by the results of the PSA (SSS_v). The Panel agreed that the revised version of SSS successfully addresses the concerns raised by the previous review panel.

The Panel noted that some assessments adopted by the PFMC (e.g. that for cowcod) were conceptually based on exSSS (MLE version). The Panel therefore agreed that in principle, exSSS was an acceptable method for conducting assessments of data-moderate stocks. However, in common with all assessments that use indices of relative abundance, any assessments based on exSSS would require adequate review of model inputs (see Section 7 below). The Panel recommended that if measures of uncertainty were required for exSSS-based assessments, they should be based on the Sample Importance Resample (SIR) algorithm (perhaps implemented using Adaptive Importance Sampling).

2.2.2 Extended Depletion-Based Stock Reduction Analysis (XDB-SRA); using models with generalized stock recruit relationships

Drs. EJ Dick and Alec MacCall outlined how DB-SRA can be implemented within a Bayesian framework, with the priors for the parameters updated using index data. The additional parameters are “q” (the catchability coefficient) and “a” (the extent of observation variance additional to that inferred from sampling error). The priors for these parameters are respectively a weakly informative log-normal distribution and a uniform distribution. The Panel noted that the uniform prior is not usually the preferred distribution for a variance parameter, but this is unlikely to have a strong influence on the results. Sampling from the posterior distribution is achieved using Adaptive Importance Sampling (AIS). Results presented showed that this algorithm was capable of successfully capturing the posterior. Dr. Dick also outlined the locus of $S_{MSY}/S_0 - R_{MSY}/R_0$ points for the current Beverton-Holt assumption underlying most Stock Synthesis assessments, along with the $(S_{MSY}/S_0 - R_{MSY}/R_0)$ space for the Shepherd stock-recruitment relationship, illustrating the region of the space that cannot be sampled owing to the structural relationships underlying the population dynamics model. Dr. Dick noted that the hybrid production function used in DB-SRA is not constrained in terms of the choices for F_{MSY}/M and B_{MSY}/B_0 .

In discussion, the Panel emphasized the importance of showing the transition from the priors for the parameters (and the inferred distributions for quantities such as the OFL) to the posteriors from DB-SRA (the post-model-pre-data distribution), which restrict the parameter space by imposing the constraint that the biomass was not negative in the past, and finally to the posteriors from XDB-SRA which account for index data. Specifically, the Panel was interested to understand whether the change to the prior distribution for M for some stocks was a consequence of imposing the biomass constraint or of fitting to the index data. The Panel felt that it is

necessary to be able to understand the reason why some indexes are down-weighted relative to others by XDB-SRA (i.e., the posterior for the parameter “a” emphasized high values). In this regard, the Panel also recommended showing the fits of the model to the index data, for example in the form of posterior predictive distributions for the index data. Such plots should be provided for any XDB-SRA assessment.

The Panel noted the AIS appeared to be performing adequately. Nevertheless, it is still necessary in applications to check that the maximum weight assigned to any parameter vector is low ($\ll 1\%$). Moreover, if the number of indexes is high, integrating out “q” and “a” should improve the efficiency of XDB-SRA. The application of XDB-SRA to northern lingcod resulted in markedly different posteriors for “a” for the two indexes, but it was not clear why this happened. The Panel recommended that the assessment for lingcod be explored further to better understand why this occurred. It was noted that the results from XDB-SRA are based on a deterministic population dynamics model and that it was possible to include process errors in the dynamics when applying SIR-based assessments. However, this may increase the computational demands of the calculations.

In relation to the form of the production function, the Panel noted that this issue was not limited to assessments for data-moderate stocks, but could be an issue for data-rich stocks assessed using, for example, Stock Synthesis. It was noted that (with the exception of codcod) the posterior distribution for B_{MSY}/B_0 for methods such as DB-SRA and XDB-SRA tend to resemble the priors, which implies that the data provide little information on the value of this parameter. Nevertheless, the posteriors for derived quantities (such as the OFL) capture the uncertainty associated with this parameter. However, estimating the parameters of a generalized stock-recruitment relationship using an approach such as Stock Synthesis could lead to estimates at the boundaries unless priors are imposed as penalties.

Dr. Dick presented XDB-SRA results for spiny dogfish and lingcod. For dogfish, the XDB-SRA estimate of depletion (posterior median 0.44) is somewhat closer to the SS value (0.63) than that from exSSS (0.23). The estimate of OFL (median 1319 t) from XDB-SRA is lower than the SS value (3041t) and higher than that from exSSS (665 t). The XDB-SRA application for northern lingcod was based on the default prior for delta (rather than the PSA value). M was updated substantially by adding the index data (tighter than the post-model-pre-data distribution). However, the XDB-SRA result was poorer than that from exSSS.

The Panel recommended that exSSS and XDB-SRA should be compared for range of actual and simulated species with different biological characteristics and exploitation history.

2.2.3 Progress report on evaluating uncertainty (σ) for category 2 and 3 stocks using simulation modeling

Chantel Wetzel presented a project she plans to do to explore the performance of management strategies based on data-moderate (Tier-2 like) and data-poor (Tier-3 like) assessment and management frameworks. She intends to evaluate SSS, DB-SRA, DCAC and XDB-SRA as well as alternative choices for the parameters which quantify the extent of scientific uncertainty associated with OFL (σ) given choices for P^* . The results will be summarized in terms of catches, the probability of overfishing, and lost yield.

The Panel noted that the operating model on which the proposed simulations will be based has a Beverton-Holt stock recruitment relationship. This may unduly favor methods such as SSS which make this assumption. It was suggested that an operating model based on a more general stock-recruitment relationship (e.g. Shepherd) be considered to examine the size of this effect. The Panel has the following additional recommendations:

- Report the bias of the estimates of the OFL.
- Report the probability of the stock dropping below the overfished threshold.
- Explore control rules which set the OFL based on the maximum of the default choice for σ and the amount of uncertainty inferred from the methods such as DB-SRA.
- Consider management strategies which set the ACL using a control rule such as 40-10. This will permit an exploration of the ability of methods such as XDB-SRA to estimate stock status.
- Report the multi-year probability of overfishing.
- Report cumulative catches.
- Consider an estimation method which bases the prior for current depletion on a vulnerability score. Testing of such of a method would need to account for the error about the PSA-depletion relationship.
- Consider combining data-moderate methods using model averaging.

2.2.4 General issues

The Panel discussed what constituted an appropriate evaluation of data-moderate methods. Most of the contributions to the workshop evaluated performance in terms of comparisons with the results of data-rich stock assessments. It was noted that care needs to be taken when making such evaluations to ensure that the number of indices included in the assessments reflected the number that would typically be available for data-moderate assessments. Furthermore, the Panel noted that the comparisons were based on predictions for a single year only and recommended that future evaluations be based on simulation testing. The Panel also recommended that the uncertainty associated with OFL estimates be computed using the approach applied by Ralston *et al.* (2011) to evaluate uncertainty in biomass estimates. This will provide guidance regarding the extent of error in OFL estimates which is already present even for Tier 1 assessments.

2.2.5 Requests by the Panel and Responses by the Technical Team

Request E: Plot depletion over time for SSS, exSS_{MLE} , $\text{exSS}_{\text{MCMC}}$, SS, SS_{V} for the stocks in Table 2 of Dr. Cope's paper.

Rationale: The comparisons presented to the Panel only considered the most recent year of the assessments.

Response: Time-trajectories of depletion from SS, exSS_{MLE} , and $\text{exSS}_{\text{MCMC}}$ were provided for canary rockfish, greenstriped rockfish, petrale sole, Dover sole, sablefish, lingcod, and spiny dogfish. The results for sablefish were notably poor. This may be attributable to the long sequence of poor recruitments which cannot be captured well by deterministic models such as exSS . The question arose of how one could diagnose whether exSS is performing poorly.

Request F: Show the fits of SS and exSS_{MLE} to the index data for the stocks in Table 2 of Dr. Cope's paper.

Rationale: The Panel wished to assess whether the fits could be used for diagnostic purposes and to understand the causes for the differences in the results for SS and exSS_{MLE} .

Response: The model fits were consistent with the data for five of the six stocks (the fits for Dover sole could not be evaluated as the exSS_{MLE} model was implemented without a catchability break in the triennial survey, unlike the SS model). The Panel concluded that it would have likely rejected the assessment for sablefish owing to the obvious residual pattern for the Combo survey (Fig. 1). The ability to diagnose poor performance is a positive feature of the exSS approach.

Request G: Plot depletion over time for SS , exSS_{MLE} , SS , SS_{V} for the stocks in Table 2 of Dr. Cope's paper. Use the revised bin structure for the SS_{V} applications.

Rationale: The response to *Request E* did not include results for SS and SS_{V} , and the Panel recommended a change to how the PSA bins are to be treated in catch-only methods.

Response: There was evidence that moving from SS to exSS improved estimation performance for five of the seven stocks (the exceptions were sablefish and spiny dogfish).

Request H: Add the relative errors for depletion and the OFL for (a) the original DB-SRA method, (b) the version of DB-SRA selected by Drs. Dick and MacCall, and (c) extended DB-SRA (all not bias-corrected) to Table 2 of Dr. Cope's document.

Rationale: The Panel wished to compare the various data-poor and data-moderate methods for a common set of stocks.

Response: There was insufficient time to run all the analyses during the workshop. The STAT provided XDB-SRA results for dogfish and northern lingcod.

2.3. Developing standardized time series index methods

Dr. Alec MacCall presented a summary of trawl survey and recreational catch/effort data for 65 unassessed West Coast groundfish species, compiled from a variety of fishery-independent and fishery-dependent sources. The purpose of this summary was to outline the data that could be used to generate abundance indices for data-moderate assessments. This summary has been appended to this report (Appendix 4) to assist Council advisory bodies in considering which stocks should be selected for data-moderate assessments.

There have been four primary fishery-independent groundfish bottom-trawl surveys on the West Coast: the AFSC triennial survey, the AFSC slope survey, the NWFSC slope survey and the NWFSC shelf-slope survey. The summary combined the NWFSC slope and shelf-slope surveys in one category, denoted the combo survey. All four surveys are commonly used in full assessments, and a number of approaches for treating the survey catch data have become established as best practice, though often without thorough evaluation or review. For example, it is common for assessments not to use 1977 triennial survey data, due to differences in depth surveyed and the large number of "water hauls," when the trawl footrope failed to establish contact with the bottom (Zimmermann et al. 2001). It has also become common to split the triennial time series between 1992 and 1995 to reflect a change in the survey timing. The Panel noted that it is important that these best practices would be well communicated between West Coast science centers. Virtually all recent assessments use a Generalized Linear Mixed Model (GLMM) method to generate abundance indices. The Panel discussed other options, for example the use of habitat-guild abundances or presence/absence, to analyze survey data within data-moderate stock assessments.

Index development may be most time-consuming part of data-moderate assessments. The technical team estimated that it will take about two weeks to develop abundance indices for a species, but then very little additional time to do the assessment. Multiple abundance indices are likely to be available for data-moderate assessments, and the assessment software should be able to accommodate these multiple indices, as well as to have the flexibility to treat them appropriately.

Recreational fisheries sampling is the major fishery-dependent source of data for abundance indices. Dr. MacCall noted that there are substantial difficulties in interpreting recreational catch rates, since various management measures have been put in place beginning in 2000, including changes to bag limits and closed areas. It is, therefore, unlikely that there will be continuity in the indices before and after 2000. The Panel recommended exploring approaches being used in other areas to account for the effect of management measures on recreational fisheries abundance indices. Other approaches, such as General Additive Models (GAM), could also be considered.

Sampling from party boat trips is likely to be the most reliable data to derive abundance indices from the recreational fishery. These data have been analyzed in some of the assessments, using Generalized Linear Models (GLMs) with county, wave and area as terms. This data source, however, has dockside and onboard sampling records combined, and it is not clear that they can be disaggregated. Nonetheless, the Central California party boat observer survey (though discontinued in 1998) can provide information on catches by site.

A summary presented showed that there is likely to be sufficient data to develop abundance indices for a number of data-poor species, including vulnerable stocks based on their PSA scores, such as china rockfish, copper rockfish, quillback rockfish, roughey rockfish and aurora rockfish.

2.4. Incorporation of length data in data-moderate assessments

Current development of data-moderate assessment methods has focused on adding abundance indices to catch-only methods. However other types of data could potentially be included in these assessments, such as length composition data. Comparisons were made using sablefish and spiny dogfish data between exSSS models with and without length composition data. These results were compared to the full stock assessment, which was considered to provide the closest approximation to the true status and biomass of the stock. The performance of all exSSS models was generally poor for both species, most likely due to the complexity of the full assessment model and the modeling decisions made to arrive at final model (e.g., weighting of various datasets). The addition of length composition data to exSSS models did not substantially improve the performance of this approach for either sablefish or spiny dogfish. Since these comparisons were made for only two stocks, it is difficult to conclude how general this result is.

The use of length-composition data in data-moderate assessment adds another layer of complexity to the analysis. Appropriate treatment of length-composition data requires estimation of selectivity patterns, which raises additional considerations which are likely to be specific to the species being assessed. A more complex assessment requires detailed evaluation, which would add to the time needed for an assessment review. At present, it is not clear that the benefit of adding length-composition data to an assessment would justify the cost of the additional time

needed to prepare and review the assessment. Therefore, for now, the Panel recommended that data-moderate assessments be limited to the use of abundance indices only.

2.5. Evaluating merits, deficiencies, and uncertainty of data-limited methods

Linsey Arnold presented a retrospective analysis comparing the results of canary rockfish assessments in 1984 and 1991 with DB-SRA and DCAC using information that was available at that time. Results indicated that DB-SRA and DCAC were not sufficiently conservative based on current understanding of canary abundance trends, but provided better estimates of sustainable yield compared to the actual assessments that were done in 1984 and 1991. As expected, performance of both methods depended strongly on the assumed level of depletion. Both methods performed extremely well when given the “correct” parameter values, suggesting that, at least in this case, most of the uncertainty in DB-SRA and DCAC is caused by uncertainty in input parameters.

Kristen Honey presented a comparison of DB-SRA and DCAC for a number of different West Coast groundfish species, again using results from full assessments as a yardstick for comparison. Both methods were relatively robust in that they tended to be consistent with full assessments. Overall both DB-SRA and DCAC tended to give lower and more precautionary estimates of the OFL, with DCAC providing the most precautionary results. The Panel recommends these comparative approaches be extended further, for example, by quantitatively comparing estimates of OFL from data-moderate and data-poor methods with estimates full assessments for multiple assessments and multiple stocks. This approach could be used to estimate the additional uncertainty due to using data-moderate or data-poor methods, which would be in addition to the uncertainty for full assessments.

3. AREAS OF DISAGREEMENT REGARDING PANEL RECOMMENDATIONS

There were no areas of disagreement regarding panel recommendations.

4. UNRESOLVED PROBLEMS AND MAJOR UNCERTAINTIES

The unresolved problems and major uncertainties for the data-moderate assessment methods are discussed in detail in Section 2. Here the Panel simply reiterates what it considers the most important issues.

- The methods being developed for data-poor and data-moderate assessments assume known historical catches, but there is considerable uncertainty in the catch estimates. This uncertainty has not been measured, and tools for incorporating this uncertainty in assessments are not well developed. This problem is not restricted to data-poor and data-moderate assessments—it is also a concern for most full assessments.
- Further work is necessary to improve inputs used in data-poor and data-moderate assessments, such as B_{MSY}/B_0 and F_{MSY}/M .
- The Panel endorsed two assessment approaches for data-moderate assessments, XDB-SRA and exSSS. However, their performance was only evaluated by comparing the results with outputs from full assessments, so the question remains of how these methods will perform in real applications. Work involving simulated population dynamics might help answer this question, and is encouraged.
- Data-moderate assessments will likely have greater uncertainty than full assessments for the simple reason that fewer data are used in the assessment. Both approaches use

different assumptions that tend to reduce apparent uncertainty, so comparisons of the estimated uncertainty between different types of assessments may not show this expected difference. For full assessments, parameters such as natural mortality and the stock-recruit steepness parameter are often fixed. For data-moderate assessments, recruitment to the stock is assumed to only depend on relative stock abundance with no year-to-year variability and selectivity patterns are fixed rather than estimated. The new data-moderate approaches fully recognize uncertainty in natural mortality and the stock-recruit relationship (both steepness and shape). Further work is needed on how to treat uncertainty in both full assessments and data-moderate assessments.

- The Panel expects that data-moderate assessments will fill an important gap in the approaches used for stock assessment in the Council process, but some experience conducting and reviewing data-moderate assessments will be necessary to better evaluate their usefulness and applicability.

5. MANAGEMENT, DATA OR FISHERY ISSUES RAISED BY THE PUBLIC AND GMT AND GAP ADVISORS

The GMT advisor highlighted the GMT's concern regarding uncertainty in historical catch estimates. The Panel agrees that this is an important consideration. The methods being developed for data-poor and data-moderate assessments assume known historical catches, and there is a need to explore sensitivity to that assumption. Since catches are equal to landings plus discard, consideration of uncertainty in discard is also important.

Scenario analysis has been typically used as a way to evaluate the impact of uncertainty in catch estimates, and this should be part of a data-moderate assessment. Ideally, the uncertainty in catch estimates should be propagated through the assessment using Bayesian approaches, though methods to accomplish this are not yet available (it should be noted that DCAC has an option to incorporate uncertainty in catch). Aside from technical difficulties, catch estimation procedures usually do not provide estimates of uncertainty, so it is difficult to gauge the extent of the uncertainty. This concern is not limited to data-poor or data-moderate assessments, though arguably this issue is of greater consequence for these assessments. There was some discussion of potential approaches during the Panel review, but all would require further development before they can be implemented. The previous data-poor review panel recommended a review of the historical catch estimates once estimates from Washington State are available, and this Panel supports that recommendation. The Panel also recommends that this review evaluate the uncertainty of historical catch estimates, including estimates of discard.

The Council staff advisor recommended that the Panel consider how data-moderate assessments should be used in the Council process. At present, category 3 assessments are used to set OFLs and ABCs, usually by aggregating estimates for individual species into stock complexes, but are not used to determine stock status relative to overfished thresholds. Data-moderate assessments should be more reliable than category 3 assessments, but in general will be less reliable than full assessments. One alternative is to use data-moderate as a filter or screening tool to identify stocks of concern that would be a priority for full assessments during the next assessment cycle.

The Council staff advisor also advised the Panel to carefully describe the process for assessing and reviewing data-moderate stocks during the next assessment cycle, including criteria for selecting stocks to be assessed, any pre-assessment activities such as data workshops,

recommended elements in the assessment, and the nature of the review process, i.e., whether by a STAR panel, the SSC groundfish subcommittee, or the SSC. The Panel agrees and has provided an outline in Section 7 below and a template for data-moderate assessments in Appendix 3.

6. RECOMMENDATIONS FOR RESEARCH AND DATA COLLECTIONS

6.1 Enhancements to catch-only methods

- Use binned PSA vulnerability scores for assessed stocks to obtain a prior for delta for use in data-poor and data-moderate assessments. Because this approach relies on a PSA analysis that was not developed for this purpose, scoring for the PSA analysis should be re-evaluated to ensure consistent time periods are used for all stocks. The year in which delta is assumed to apply should be consistent with the scoring period.
- Further develop meta-analysis methods for the ratios B_{MSY}/B_0 and F_{MSY}/M . While large-scale meta-analysis provides valuable information, synthesis of assessment results on a regional scale is likely to be more useful in determining priors. This is because the quality of the assessments going into the meta-analysis can be ascertained and consistent definitions for these quantities are used regionally. A comparison of regional results with global results would also be valuable.
- Compare the new 3-parameter stock-recruit relationship implemented in SS (Taylor et al. 2012) with the hybrid production function in DB-SRA and XDB-SRA.
- The prior for natural mortality developed by Dr. Owen Hamel, and used extensively in the previous assessment cycle, should be adequately documented and reviewed.

6.2 Extended DB-SRA and SSS

- XDB-SRA and exSSS are endorsed for use in data-moderate assessments in the next assessment cycle (see table 2 for distinguishing characteristics of the two approaches). The management strategy evaluation described in Section 2.2.3 may be informative about relative merits of the two approaches. A WebEx seminar for interested scientists should be conducted in Spring 2013 to present results from simulation testing comparing XDB-SRA and exSSS.
- The Sample Importance Resample (SIR) algorithm (perhaps implemented using Adaptive Importance Sampling) should be used to quantify uncertainty for exSSS-based assessments, should measures of uncertainty be required.
- The ability to incorporate a prior on depletion may be useful feature of data-moderate assessment that adds robustness to results. exSSS does not currently have this capability. A variant of exSSS should be developed that incorporates a prior for depletion (delta). This variant may be useful bridge between SSS and exSSS as they are currently implemented.
- The uncertainty associated with OFL estimates should be computed using the approach applied by Ralston *et al.* (2011) to evaluate uncertainty in biomass estimates. This will provide guidance regarding the extent of error in OFL estimates which is already present even for Tier 1 assessments. Systematic comparison of OFL estimates from data-moderate and data-poor assessments with estimates from full assessments may allow estimation of the additional uncertainty due to the use of these methods.

6.3 Development of abundance indices for use in data moderate assessment

- Consider alternative ways of developing abundance indices for surveys, such as post-stratification to more closely match the species presence and distribution, or developing indices based on presence/absence or stock distribution.
- It is not necessary to omit all recreational fishery data after 2000 due to regulatory changes. Instead an attempt should be made to account for management changes such as changes to area and bag limits to the extent possible in index development. Conduct a literature review to determine best practices in developing indices from recreational fishery catch and effort data, with particular attention on methods for dealing with potential sources of bias due to regulatory changes, such as closed areas and bag limits. Focus on regions where this expertise is most advanced, such as the Southeast US.

7. RECOMMENDATIONS FOR THE ASSESSMENT AND PEER-REVIEW OF DATA-MODERATE ASSESSMENTS

- The NMFS Science Centers should develop a list of stocks for which the indices of abundance can be justified as likely to be related to abundance.
- The Panel had extensive discussion regarding the number of stocks that should be reviewed during a STAR panel. Arguments for keeping the number low focused on the concern that these assessments are based on new approaches, and there will be some learning involved both in developing the assessment and reviewing it. Arguments for a higher number of assessments included that more assessments are likely to be rejected or not even carried forward for review due to insurmountable difficulties. In addition, there would be more opportunity in learning from more assessments with contrasting features. Perhaps the best way to deal with this issue is to identify 6-12 stocks from the list developed by the NMFS science centers, but plan to drop the most dubious assessments before the STAR panel review.
- The assessments to be presented to the 2013 data-moderate assessment STAR panel should include stocks whose assessments would be based on the NMFS bottom trawl survey, and those for which the primary index of abundance would be a CPUE index derived from recreational catch and effort data. Carrying forward two groups of stocks with similar habitat and fishery characteristics provides both contrast and potential efficiency, since similar analytical approaches are likely to be applicable within each group.
- A data workshop should be held to focus on development of suitable indices for data-moderate assessments. Alternatively (and perhaps preferably), a concerted effort should be made to establish good communication among the core group conducting the data-moderate assessments to share ways of filtering and analyzing data, and promote adoption of consistent modeling approaches.
- The assessments presented to the 2013 data-moderate assessment STAR panel should not use age- or length-data. Assessments which use such data are likely to require more extensive review that is possible during the data-moderate STAR panel.
- Data-moderate stock assessments should follow the template in Appendix 3.
- The first review of data-moderate assessments should be conducted during a STAR Panel, but future reviews could be conducted by the SSC or its groundfish sub-committee. For this cycle, modeling approaches other than XDB-SRA and exSSS should not be used due to lack of time to conduct an adequate review of the method during a

STAR Panel (however refinements to XDB-SRA and exSSS are permissible). The independent panelists at the data-moderate panel should be selected to provide expertise on survey design and analysis of recreational CPUE data.

- At present, both modeling approaches (XDB-SRA and exSSS) are considered appropriate for data-moderate assessments. Comparison of alternative models (both XDB-SRA and exSSS) is encouraged. It is acceptable to present an assessment using a single modeling approach, but the choice of modeling approach should be justified. The STAR Panel will make requests of the STATs, but will not impose an alternative method on the STAT if they believe this is not appropriate for the stock concerned. The STAT may change their best model, but the Panel's job is to review what is presented by the STAT. The Panel will recommend adoption / rejection of the "best model." The STAR Panel will be charged with identifying a preferred approach in the event that both models are presented.
- Data moderate assessments should be used for deriving OFLs, ABCs, and ACLs. In addition, data-moderate assessments should provide estimates of the probability the stock is in each of three categories: less than $B_{25\%}$, between $B_{25\%}$ and $B_{40\%}$, and greater than $B_{40\%}$. The Panel recommends that these results not be used for status determination, but rather to identify whether there is potential concern with stock status, and to prioritize stocks for a full assessment in which all available information is considered.
- The SSC will review the assessment and the STAR Panel report. The key output from this exercise is an OFL and ABC, which addresses possible overfishing. If there is a sizeable probability the stock is in an overfished state (higher than 40%, for example), the SSC will recommend that a full assessment be conducted at the earliest opportunity. The Council may wish to implement management changes in pro-actively.
- The Panel was informed that the NWFSC has a 'stock assessment handbook' which includes a summary of key common assumptions when making assessments and recommended that it be made available to all assessment authors.

Table 2. Comparison of the features of XDB-SRA and exSSS.

	<i>XDB-SRA</i>	<i>exSSS</i>	<i>Comments</i>
<i>Population dynamics</i>	Biomass difference model	Age-structured	An age-structured model can be adapted to unique stock characteristics.
<i>Stock regeneration</i>	Pella-Tomlinson joined to a Schaefer curve at low stock size	Beverton-Holt SRR	The hybrid production function in XDB-SRA has greater flexibility. Beverton-Holt is the standard approach for full assessments
<i>Leading parameters</i>	B_{MSY}/B_0 , F_{MSY}/M , M , delta (depletion), catchability, extra variances	M , steepness, B_0 , catchability	XDB-SRA is parameterized using leading management parameters; exSSS uses the same leading parameters as full assessments. XDB-SRA includes a prior on depletion, which may add robustness.
<i>Treatment of uncertainty</i>	Fully Bayesian; posterior distribution obtained using SIR with AIS, estimation of additional variance terms	MLE with Hessian approximation, or MCMC	XDB-SRA has more comprehensive treatment of uncertainty. For exSSS, the samples from MCMC often show signs of poor convergence of the MCMC algorithm, and asymptotic variance based on the Hessian is a questionable approximation.
<i>Software</i>	Purpose-built, coded in R. Long run times to generate posterior distributions with present computing capacity.	Simple stock synthesis model	XDB-SRA has limits on the number of indices that can be used in the assessment, and limits on how catchability can be modeled (e.g.: power relationship, catchability breaks, catchability trends, etc). Some of these problems may be overcome by integrating out the priors for q and a analytically. Stock Synthesis is a well-established software package for stock assessment, with lower likelihood of programming errors, and greater flexibility in modeling catchability and selectivity patterns. SS is not limited in the number of indices that can be used or the modeling choices. Allows a smoother bridge between data-poor assessments and full assessments. Stock synthesis has greater complexity, but much of that complexity is not used in exSSS.

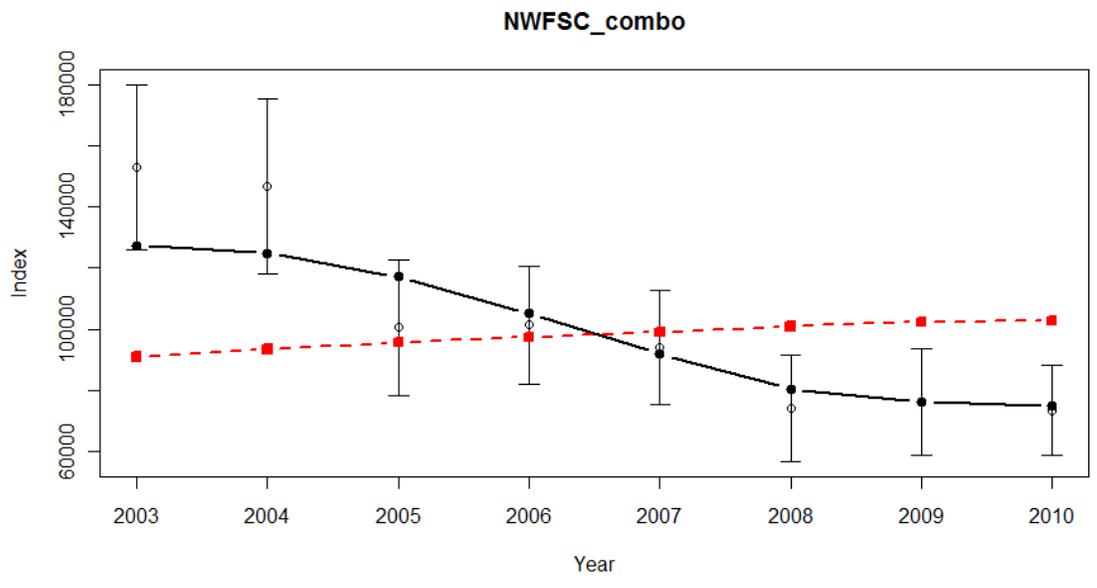

Figure 1. Fit of $exSS_{MLE}$ (red, solid squares) and SS (block, solid circles) to the NWFSC Combo index for sablefish. Example of an unacceptable residual pattern that would provide a rationale for rejection of a data-moderate assessment.

Appendix 3. Proposed template for a data-moderate assessments

1. Title page and list of preparers – the names and affiliations of the stock assessment team (STAT).
2. Introduction: Scientific name, distribution, basic biology (growth, longevity, ecology), the basis for the choice of stock unit(s)(no more than 1-2 paragraphs).
3. Development of indices (used and rejected). Novel approaches should be fully documented.
4. Survey of other data available for assessment: sample sizes by year and source of lengths, and ages (read and unread)--in case there is interest in conducting a full assessment in the future.
5. Selection of method (exSSS or XDB-SRA; authors “encouraged” to do both).
6. Assessment reporting
 - a. Specification of priors / production function (defaults OK)
 - b. Initial runs using catch-only methods (DB-SRA or SSS (or both))
 - c. Diagnostics
 - i. Evaluation of convergence
 - ii. Residual plots
 - iii. Posterior predictive intervals (if Bayesian)
 - iv. Time-trajectories of biomass, depletion, etc.
 - v. Sensitivity analyses using alternative catch streams, alternative priors for depletion, etc.
7. Estimates of OFL (median of the distribution), and the probability that that the stock is in each of three status categories: less than $B_{25\%}$, between $B_{25\%}$ and $B_{40\%}$, and greater than $B_{40\%}$.

Abstract

This report documents time series of data on abundance of 65 species or stocks of unassessed west coast groundfish managed by the Pacific Fishery Management Council. These data are derived mainly from various fishery-independent bottom trawl surveys conducted since 1977, and various recreational fishery monitoring programs conducted since 1975. By supplementing Depletion-Based Stock Reduction Analyses (previously used for estimation of overfishing limits) with these data on abundance trends, it should be possible to elevate a substantial number of these data-limited stocks to the status of “assessed.”

1. Introduction

Of the approximately 90 species or stocks of west coast groundfish managed by the Pacific Fishery Management Council (PFMC), about 60 remain unassessed. In order to provide the PFMC with a basis for setting Annual Catch Limits, Dick and MacCall (2011a,b) were able to calculate overfishing levels for most of these unassessed stocks using a method they called Depletion-Based Stock Reduction Analysis (DB-SRA). By supplementing DB-SRA with data on trends in abundance, it may be possible to upgrade the status of these analyses, thus providing minimal assessments for many of these stocks. This summary describes and quantifies most of the available sources of historical abundance information, and allows an initial evaluation of the feasibility of conducting DB-SRA assessments.

The sources of information considered in this document are summarized in the following table:

Name	Gear	Spatial Resolution	Time Span
Triennial Shelf Survey	Bottom Trawl	Site	1977-2004
Slope Survey	Bottom Trawl	Site	1984-2001
Combo Survey	Bottom Trawl	Site	1998-2010
RecFIN Monitoring	Hook and Line	County	1980-2003
Southern California Partyboat Observers	Hook and Line	Block	1975-78, 86-89
Northern California Partyboat Observers	Hook and Line	Site	1987-1998

There are additional sources of information that may potentially be useful. The Northwest Fisheries Science center has conducted a hook and line survey since 2004 in Southern California for most of the past decade (described by Harms et al. 2010). The California Cooperative Oceanic Fisheries Investigations ichthyoplankton surveys have been conducted in Southern and Central California waters since 1950, and provide abundance information on some species. In Southern California, entrainment estimates by electrical generating stations, and trawl surveys by some sanitation districts may in some cases provide useful time series of information on relative abundance.

2. Sources

We describe the principal surveys and fishery monitoring programs that are of greatest general utility, summarizing them by the number of positive samples for each year. Geographic and temporal coverage, and sample sizes vary substantially, but surveys covering multidecadal time spans are potentially the most informative. Some of the earlier surveys did not identify all relevant species, in which case no positive samples appear in the individual species summaries for those years. The data have been summarized by major west coast fishery management regions: North is Cape Mendocino to Cape Flattery, Central is Pt. Conception to Cape Mendocino, and South is the Mexican border to Pt. Conception. Pt. Conception is defined as 34.55 N Lat (decimal), and Cape Mendocino is defined as 40.167 N Lat (decimal).

3.1 Scientific Surveys

3.1.1 Triennial Shelf Survey

The Triennial Shelf Survey (or “Triennial”) conducted by the AFSC and NWFSC utilized chartered commercial trawlers to survey North and Central area waters from 1977 to 2004. Coverage of these areas varied substantially among survey years by latitude (Table 1) and by depth (Figure 1). Years 1980, 1983 and 1986 ended near Monterey and did not extend to Pt. Conception (Lat 34.55N).

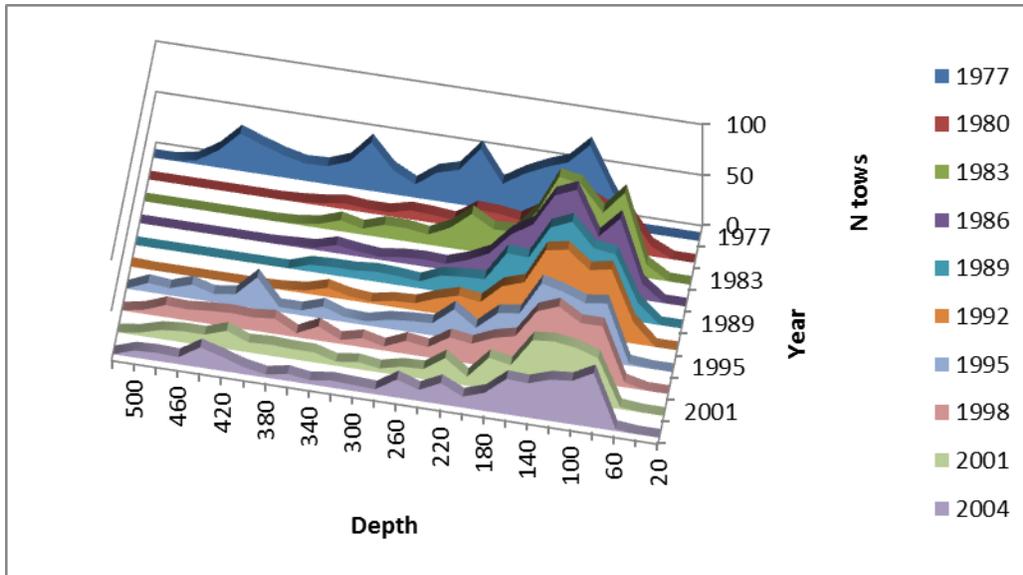

Figure 1. Frequency of Triennial Survey samples by depth (fathoms) and year.

Table 1. Number of trawl hauls conducted by the Triennial Survey.

3.1.2 Slope Survey

The slope survey was conducted irregularly from 1984 to 2001 by the AFSC, but only provides comprehensive coverage of depths and latitudes (Northern and Central Regions) beginning in 1997 (Table 2). The earlier years consisted of local studies (Figure 2). There was an increased sampling of deeper waters (values in fathoms) later in the time series (Figure 3). Earlier years also had an incomplete listing of taxa.

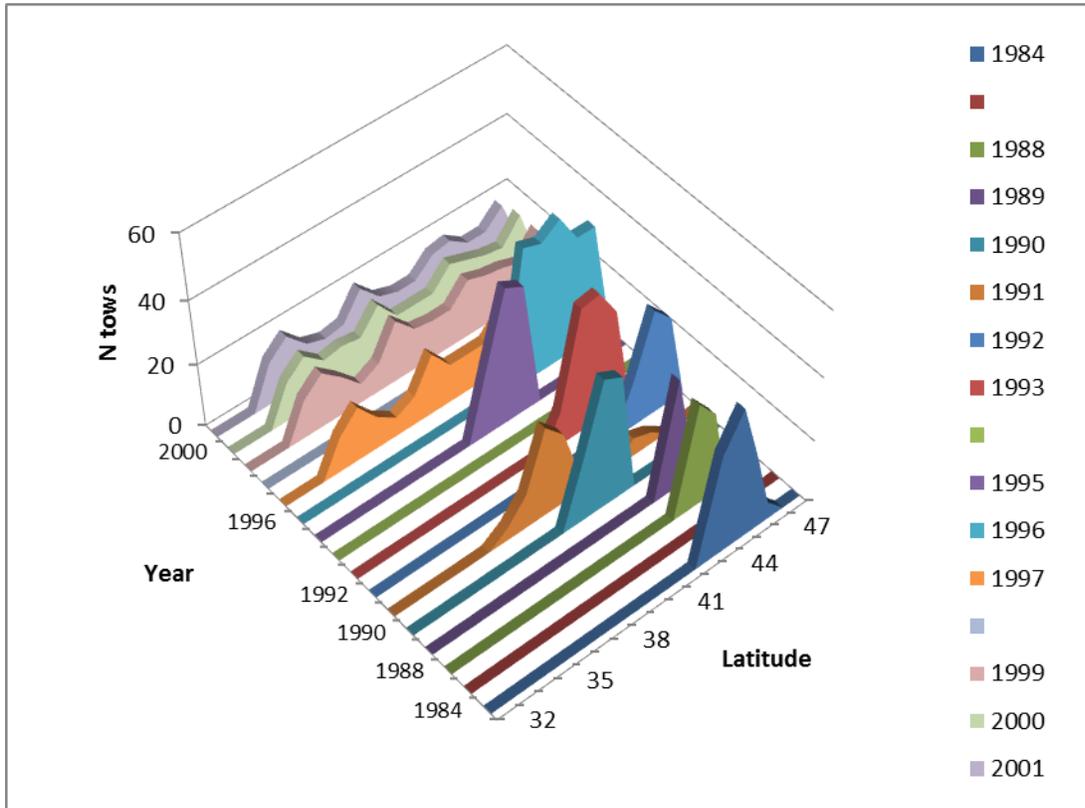

Figure 2. Latitudinal coverage of the Slope Surveys.

3.1.3 Combo Survey

The West Coast Shelf/Slope Bottom Trawl Surveys (a.k.a, Combo Surveys) were initiated by the NWFSC as a successor to the Slope and Triennial Shelf Surveys that had been inherited from the AFSC (Bradburn et al., 2011). The Combo Surveys achieved a broad and consistent coverage of latitudes and depths (Table 3), and included waters south of Pt. Conception beginning in 2002. The list of identified taxa in 1998 was incomplete.

Table 3. Number of tows by the Combo Survey, by year and latitude. Latitude groups compare approximately to North, Central and Southern Regions.

3.2 Recreational Fishery Sampling

3.2.1 Partyboat Trips

The RecFIN database contains data for recreational trips sampled by the MRFSS program beginning in 1980. For most purposes, the most useful samples come from partyboat (a.k.a. “commercial passenger fishing vessels” or CPFVs) trips. The sampling program was conducted in four regions: Washington, Oregon, and north and south of Pt. Conception California. The Washington samples are of little use and are not considered here. The North Region reported here consists of combined samples taken in Oregon and in California north of Cape Mendocino. The Central Region is represented by the remainder of Northern California samples, covering the coast from Pt. Conception to Cape Mendocino (Central Region partyboat data from years 1997 and 1998 are anomalous and have been deleted for the present purpose). Sampling was conducted by two-month “wave” and by county (Tables 4-9). Although recreational fishery sampling is ongoing, the data reported here extend only through 2003 after which the catch rates were severely impacted by restrictive bag limits and area closures. For the present purpose, the unit of sampling is a completed trip (which may have visited multiple fishing sites), and describes the combined catches by all of the sampled fishermen on that trip.

Although the trip-level data used here are based on sample data downloaded from RecFIN (<http://www.recfin.org/>), these trip-level summaries are not easily reconstructed from that source, and required substantial manipulation of the query results. Sample data from Northern California and Oregon have been examined and edited for problematic entries, and are available from CALCOM (URL 128.114.3.187). Southern California data have yet to be “cleaned-up”, but a spreadsheet database can be obtained by request to the senior author (Alec.MacCall@noaa.gov).

3.2.2 On-board Observers

The State of California conducted on-board partyboat sampling in the Southern and Central Regions. Large numbers of Southern California partyboat trips were sampled during 1975-1978, and again during 1986-1989 (sample sizes for individual species are for each four-year period combined). These data are available from the California Department of Fish and Game, but pose some difficulties in defining equivalencies, including locations for the two time periods. The Central Region was sampled from 1987 to 1998, with detailed identification of individual fishing sites, and the data (available from the California Department of Fish and Game) are relatively easy to work with. Because the Central California data are identified by fishing site, there is no convenient general summary statistic for sample size, but the species tables report numbers of fish observed by species.

Table 4. Number of partyboat trips sampled in Northern Region (Northern California and Oregon) by two-month wave.

3. Relative Abundance

The survey and monitoring data require a substantial amount of processing to be useful for stock assessment. Often, filtering the data based on co-occurring species, depth, location, or other consistent habitat attributes (e.g., by the logistic regression method of Stephens and MacCall 2004) allows identification of an appropriate subset of the data for the target species. Although swept-area estimates of abundance are possible and have been produced for some of these trawl surveys, a common statistical approach to developing indexes of relative abundance is to employ a General Linear Model (GLM) with factors such as year, location and season (Maunder and Punt 2004). For sparse data (i.e., containing frequent zeroes), it may be useful to use a delta-GLM approach, where a log-linear model is used for the abundance at positive stations, and a joint logistic (or similar) regression is used to describe the probability of a positive observation. In either case, the values of the “year” effects are a

basis for the desired annual indexes, provided interaction terms involving “year” can be ignored. Importantly for the less common species, the data may be too sparse to estimate index values for individual years in which case it may be appropriate to aggregate the abundance data into time-blocks of years.

4. Additional information

Only partyboat-based sampling is included in these summaries, but other sampled segments of the recreational fisheries such as private boats may be useful in some cases such as brown and grass rockfish and kelp greenling. CalCOFI ichthyoplankton surveys may be useful for Mexican rockfish and for several species of flatfishes. For some deep water Southern California rockfishes such as bronzespotted and pink it may be possible to develop an absolute estimate of abundance in recent years based on sightings in submersible surveys conducted for cowcod (Yoklavich et al. 2007). No useful source of information was found for soupfin shark. Dusky rockfish are exceeding rare on the US West Coast which is at the southern end of the species’ range, and do not merit consideration. No useful information was found for four small species of rockfishes (chameleon, freckled, harlequin and pinkrose) that are seldom encountered or retained, and may be difficult to identify.
